

Project Title : Financial Health Score Analysis

Many individuals earn income but still struggle with financial stability due to excessive spending, low savings, and high debt obligations. Financial institutions and fintech platforms aim to evaluate users' financial behavior in order to assess financial health and provide personalized financial recommendations.

The objective of this project is to analyze user financial behavior by examining income, expenses, savings, and debt payments. Using these variables, a financial health scoring model is developed to measure financial stability and classify users into different financial risk categories.

The project simulates financial transaction data for users and applies data analytics techniques to derive financial indicators such as savings ratio, spending ratio, and debt burden. These indicators are combined to compute a Financial Health Score, which helps identify financially healthy users and those at financial risk.

The final analysis is visualized through an interactive Power BI dashboard that highlights financial patterns, user segmentation, and key insights that can assist financial institutions in understanding customer financial behavior and risk levels.
